

# Radioactivity

## Lecture 13

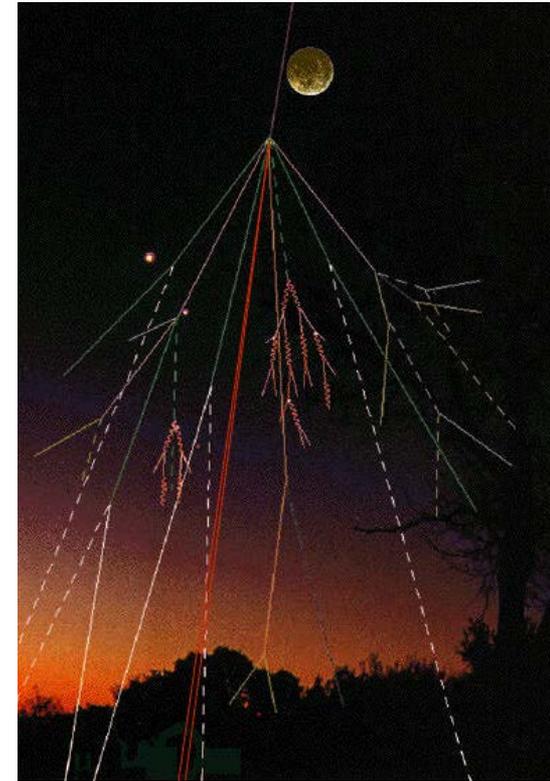

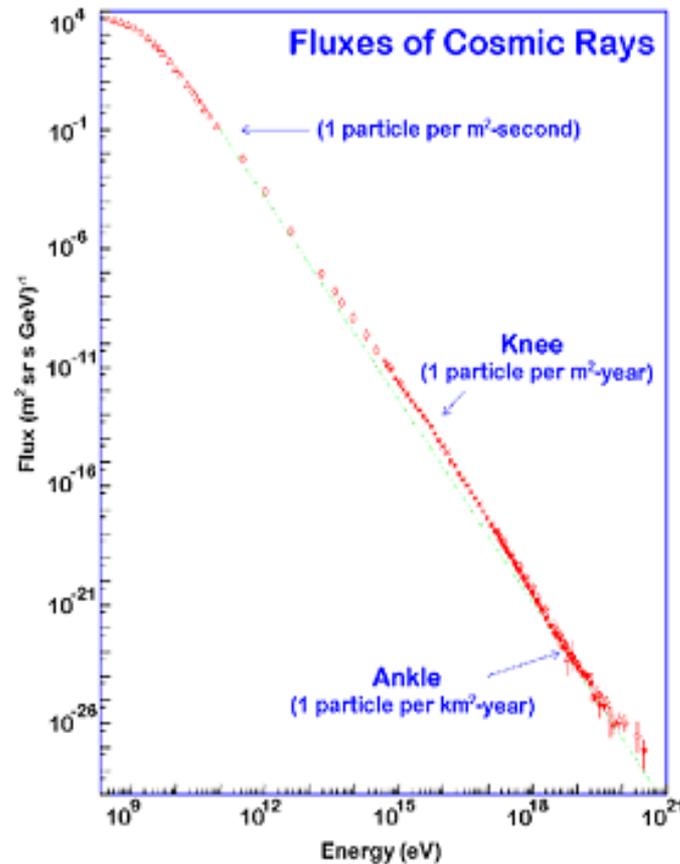

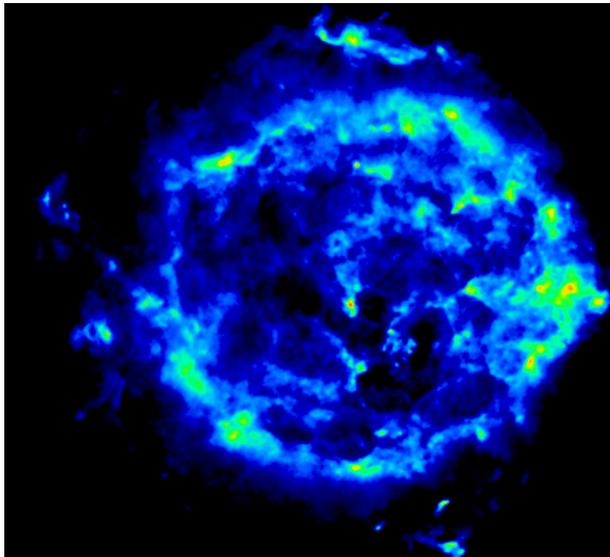

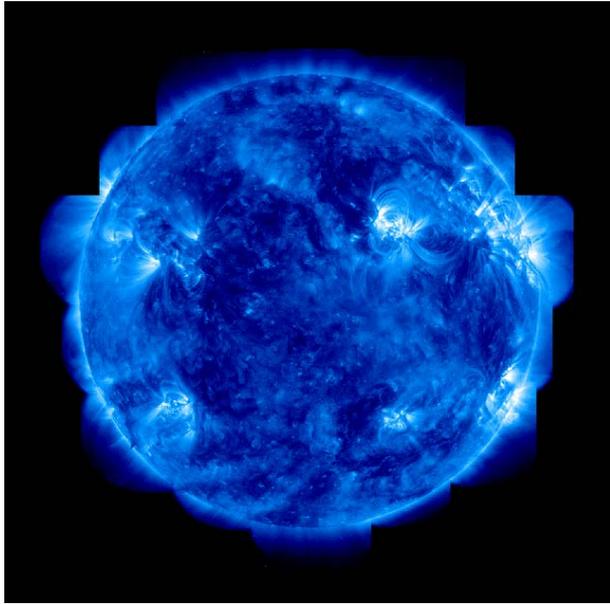

### Radioactivity in the Atmosphere

# Cosmogenic Radioactivity

Bombardment of the atmosphere by intense high energetic particle radiation (electrons, protons, and heavy elements) produced and accelerated by the magnetic field of the sun (solar activity cycle) and by distant cataclysmic events such as supernovae.

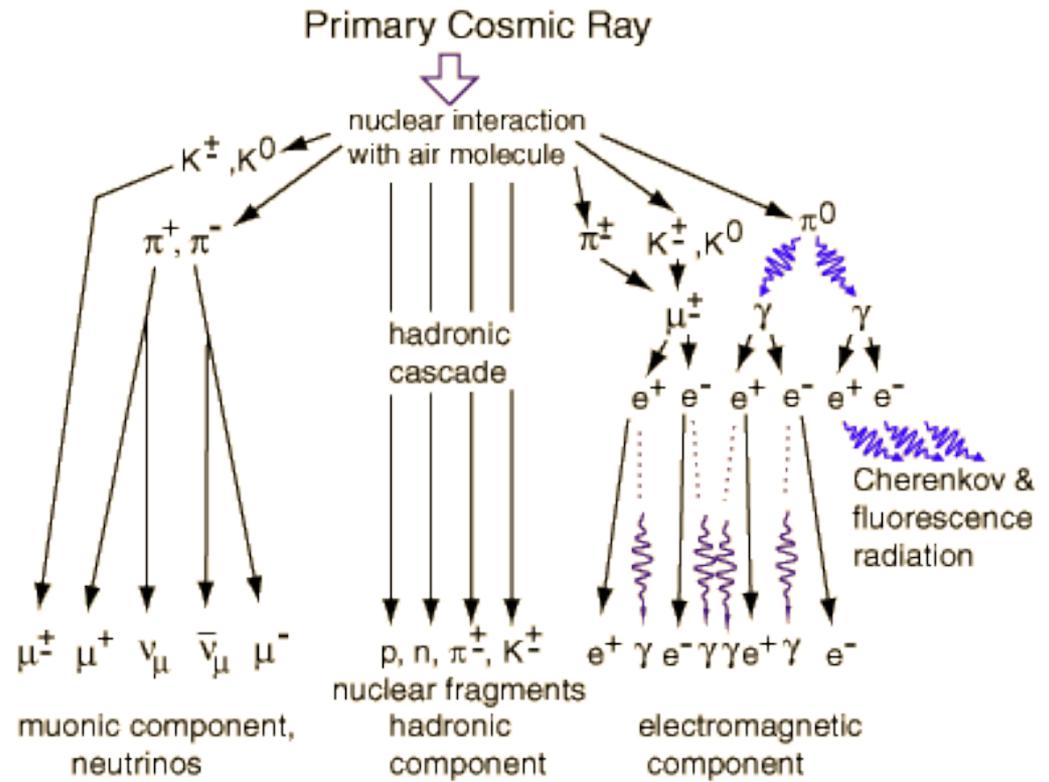

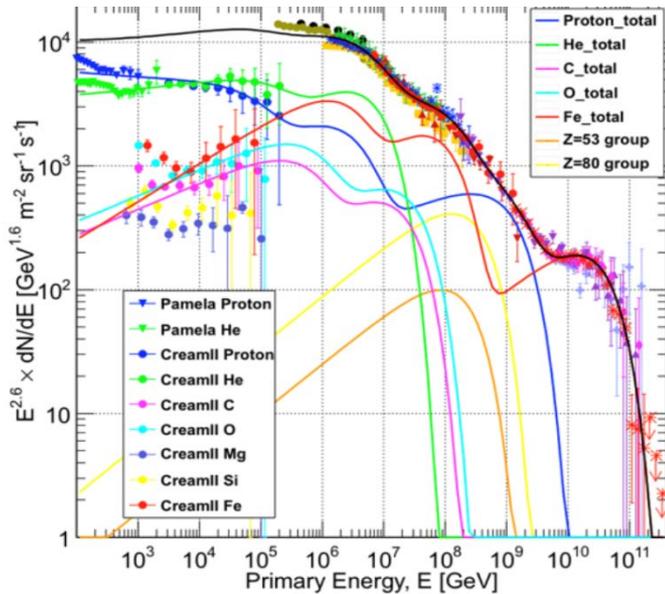

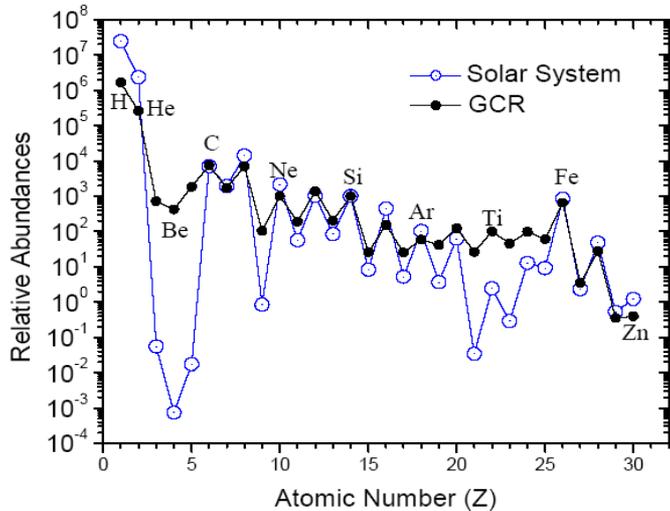

# Origin and nature of cosmic rays

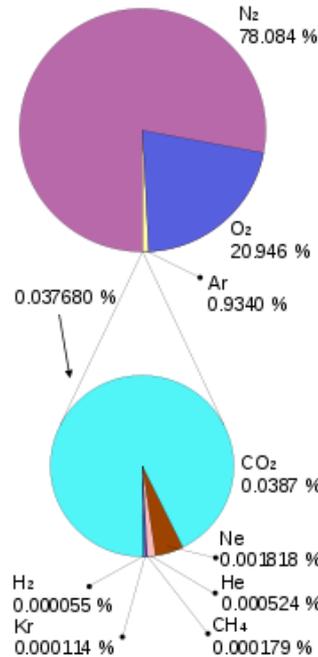

Cosmic rays cover a wide energy range, depending on the source (sun to distant supernova). The cosmic rays cause spallation effects in the atmosphere generating a secondary radiation flux of high energetic and often radioactive particles.

# Composition of Cosmic Radiation

Initial composition changes by spallation reactions generating a high flux of energetic secondary hadronic and elementary particles, the air shower.

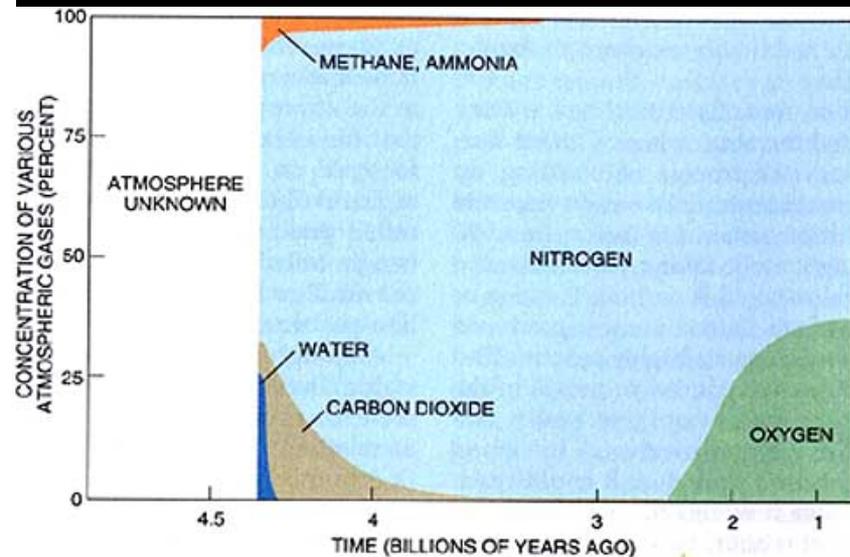

# Composition of the Atmosphere

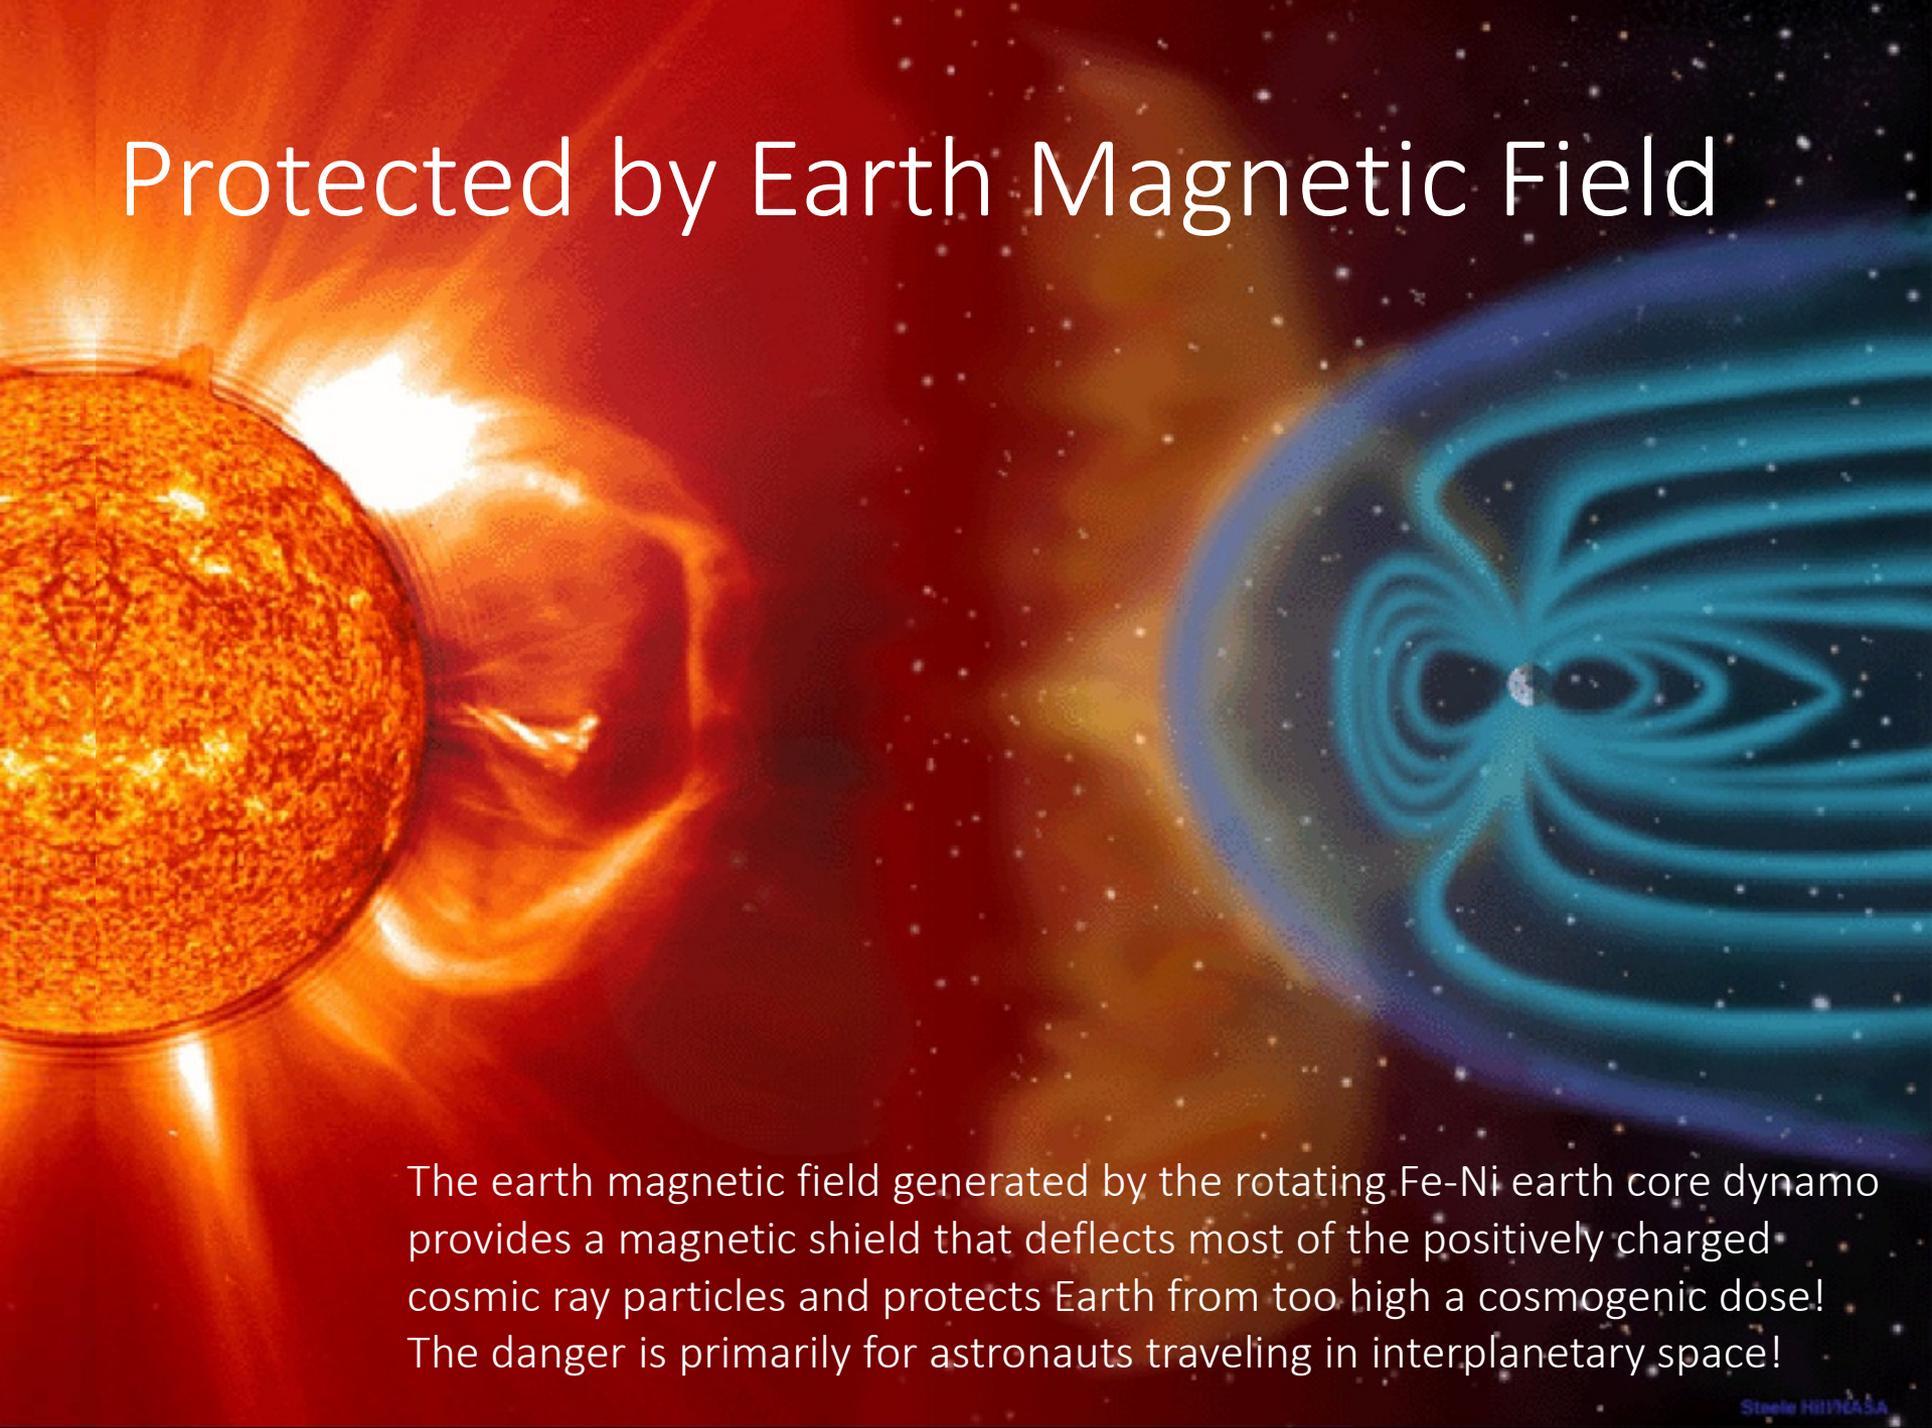

Gas Name	Chemical Formula	Percent Volume
Nitrogen	N <sub>2</sub>	78.08%
Oxygen	O <sub>2</sub>	20.95%
*Water	H <sub>2</sub> O	0 to 4%
Argon	Ar	0.93%
*Carbon Dioxide	CO <sub>2</sub>	0.0360%
Neon	Ne	0.0018%
Helium	He	0.0005%
*Methane	CH <sub>4</sub>	0.00017%
Hydrogen	H <sub>2</sub>	0.00005%
*Nitrous Oxide	N <sub>2</sub> O	0.00003%
*Ozone	O <sub>3</sub>	0.000004%

\* variable gases

The earth atmosphere is not a constant entity, but subject to changes due to geo-chemical processes and developments, radioactive decay induced emissions such as Argon and Helium, and cosmic ray induced reaction processes

# Protected by Earth Magnetic Field

The earth magnetic field generated by the rotating Fe-Ni earth core dynamo provides a magnetic shield that deflects most of the positively charged cosmic ray particles and protects Earth from too high a cosmogenic dose! The danger is primarily for astronauts traveling in interplanetary space!

# Cosmic ray induced mutation?

[www.CartoonStock.com](http://www.CartoonStock.com)

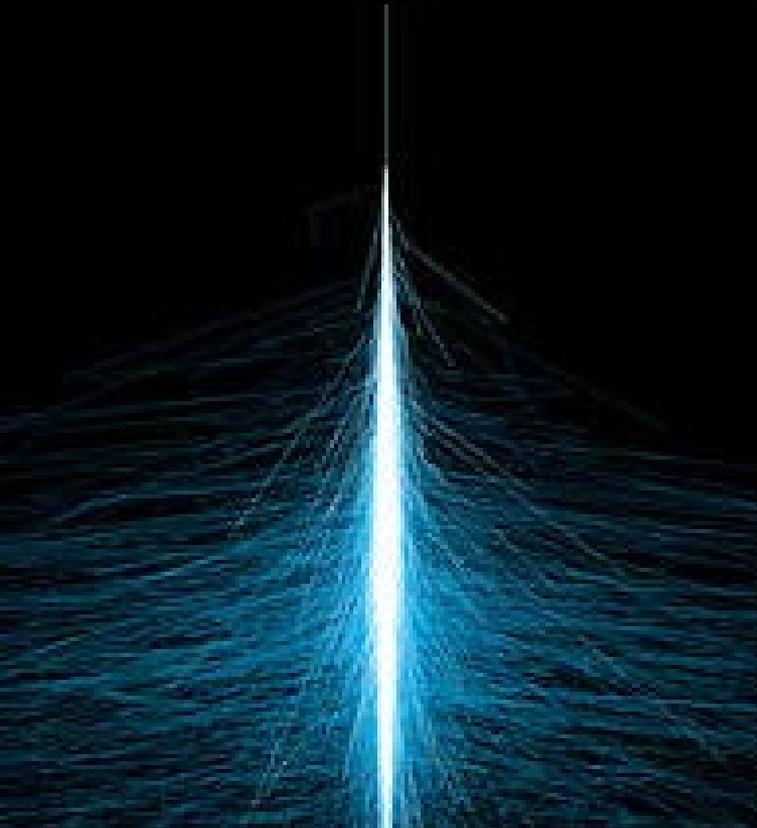

Cosmic ray triggers mutation processes by affecting the molecular structure or sequence of DNA sections, causing the mutations that may have driven the evolution of life.

"There's evolving like mad — You put in way too many cosmic rays!"

# Cosmic Ray Shower Development

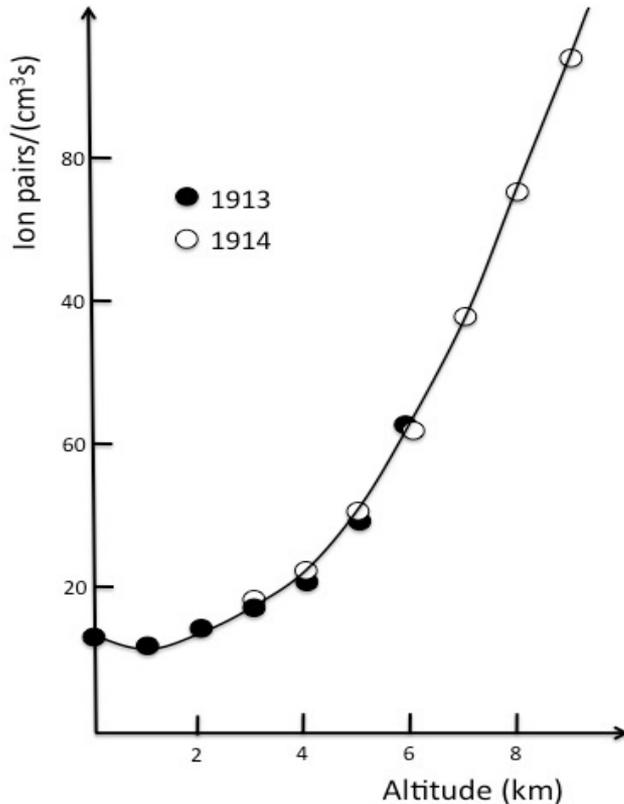

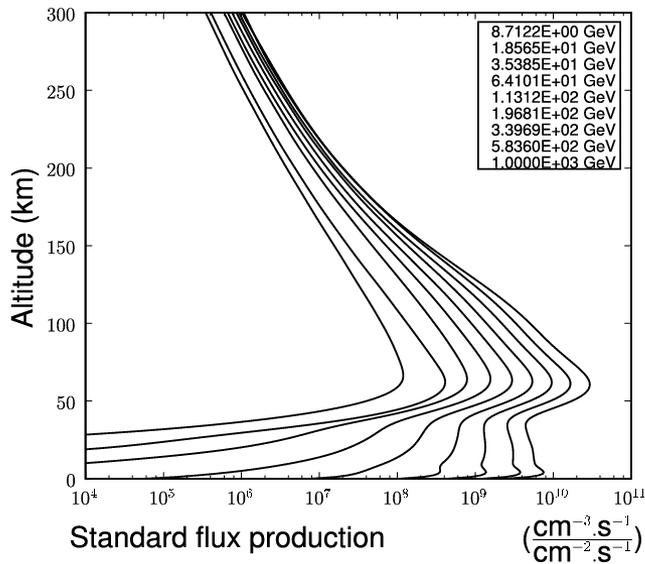

through secondary interaction of cosmic particle in atmosphere

Multiple reactions of incoming high energy particle with air causes spallation of air molecules, atoms, and nuclei and fragmentation of incoming heavy ion components!

# High Altitude

Maximum exposure is near stratospheric altitude because of interaction probability of incoming ray with atmospheric particles. At lower altitudes sea-level to mountain level you experience an increase in cosmic ray exposure roughly doubling with every 1500 m. High exposure to mountain populations, air personnel, and frequent flyers.

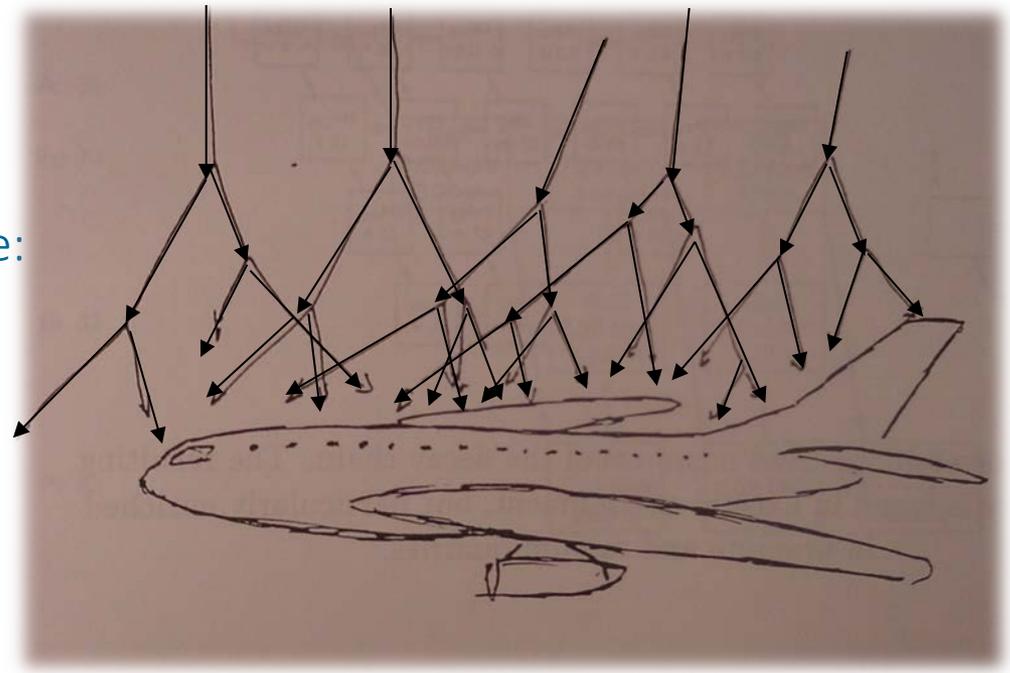

# Cosmic Rays in High Altitude

Earth is relatively protected from cosmic rays through atmosphere shield; typical exposure is  $D=0.04 \mu\text{Sv/h}$ . Mountain climbers and airline crews and passengers are exposed to higher doses of radiation. Dose doubles every 1500 m in height. At 1.5 km altitude  $D_{(h=1500m)}=0.08 \mu\text{Sv/h}$ . At 10 km height dose is about 100 times sea-level dose  $D=5 \mu\text{Sv/h}$ .

$$D_{(h_n=n \cdot 1500m)} = 2^n \cdot D_{(h_0)}$$

Example: Total dose  $D$ :

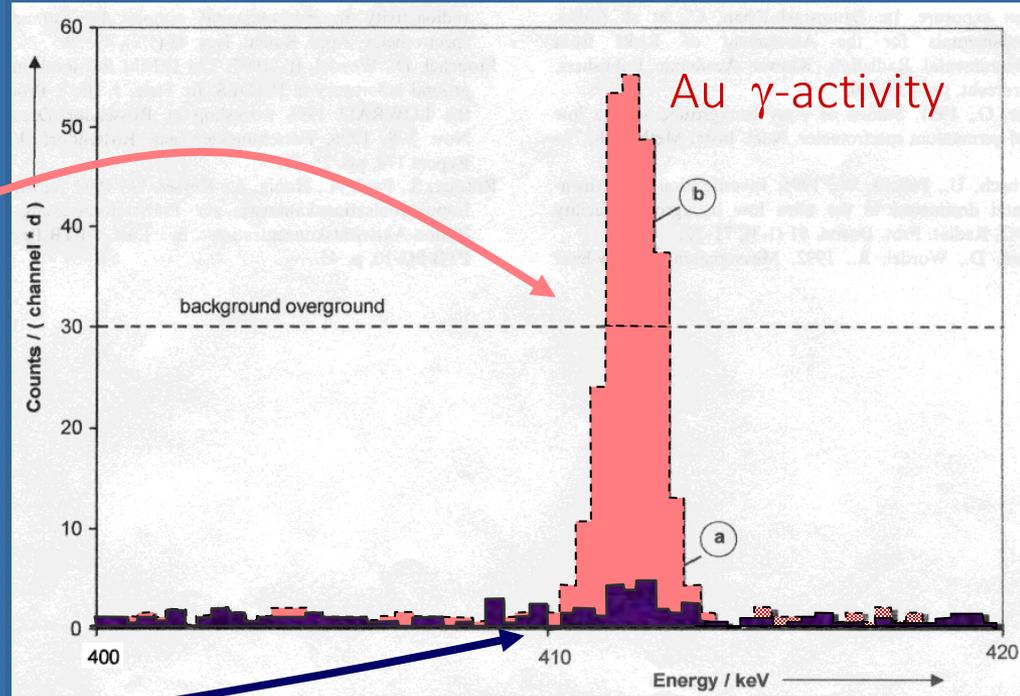

- after 10h of flight in 10km altitude:  
 $D=5.12 \mu\text{Sv} \cdot 10\text{h} = 0.0512 \text{ mSv}$ ,
- for round trip:  
 $D=0.1 \text{ mSv}$
- Frequent flyer with about  
3 transatlantic flights/year  
 $D=0.3 \text{ mSv/year}$ .

Compare to natural dose ( $\sim 0.3 \text{ mSv/y}$ ) !

# Observable Effects in Activation by Neutron Capture!

Wife's ring with ground level dose!

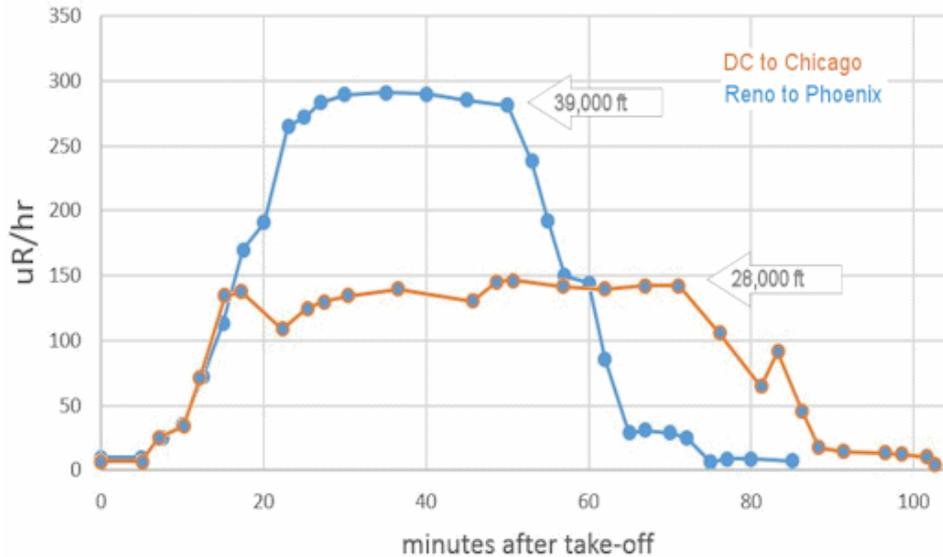

Husband's ring with transatlantic high altitude dose

⇒ 8 times more dose

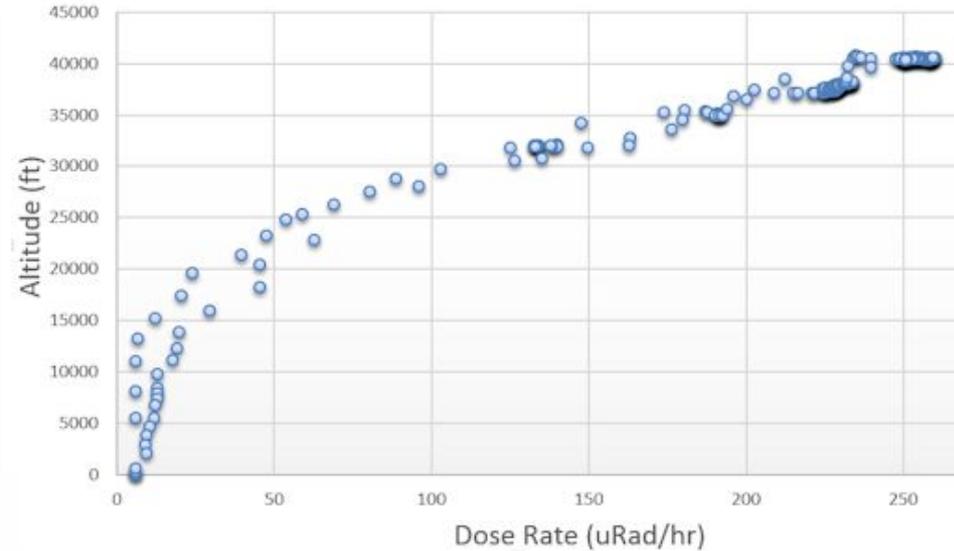

# Radiation Dose per Altitude

In-flight Radiation Dose Rates

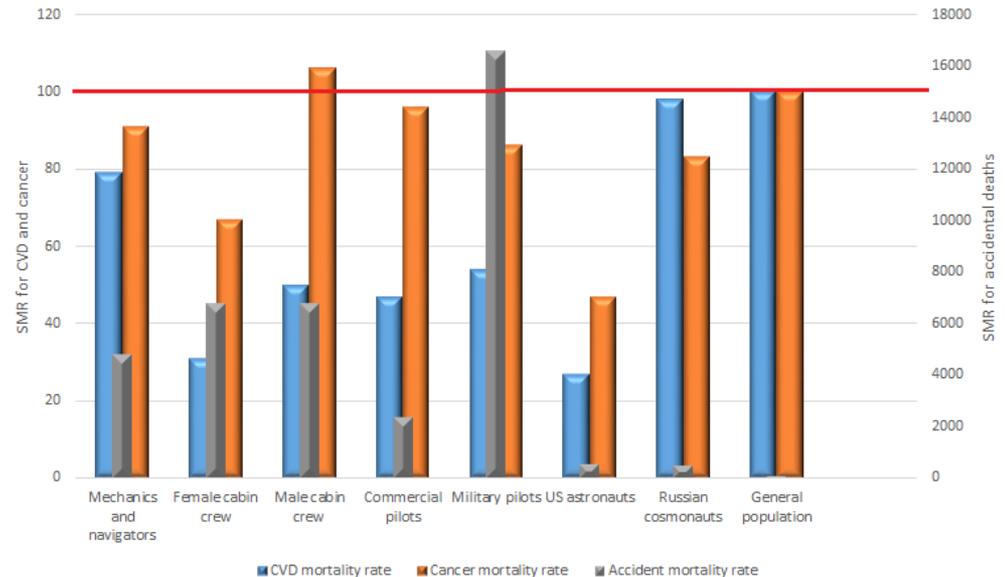

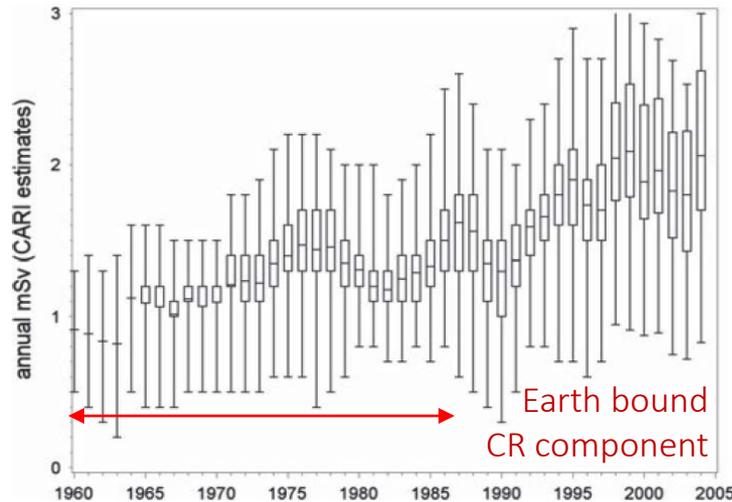

Radiation Dose Rate vs. Altitude

$$1 \text{ Gy} = 100 \text{ Rad} \quad 1 \text{ Rad} = 0.01 \text{ Gy}$$

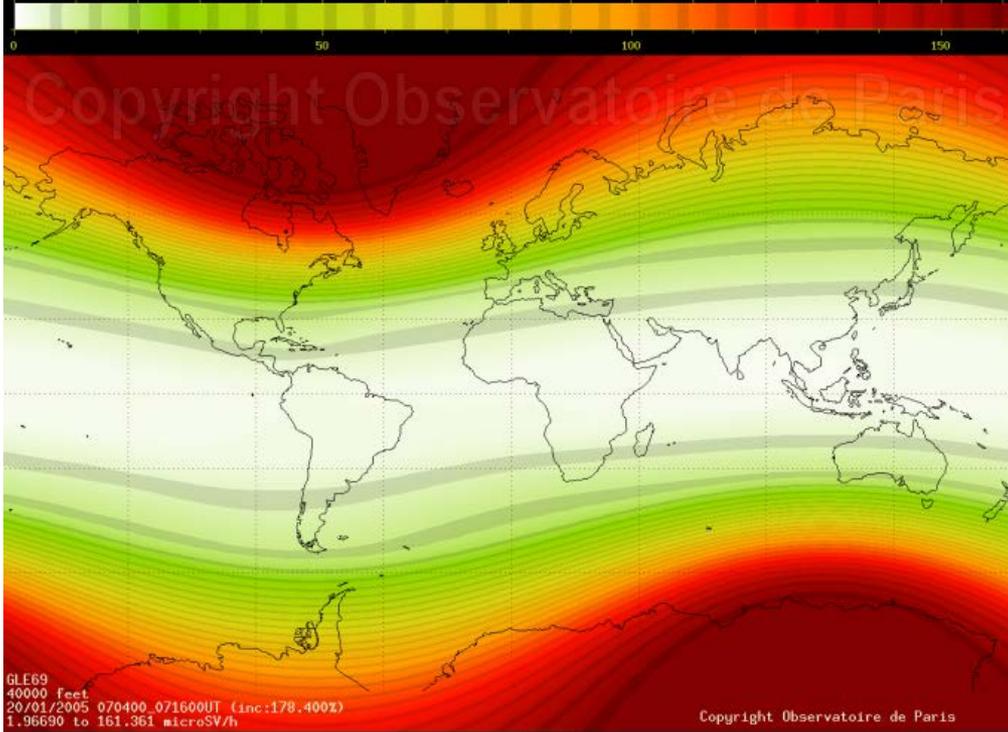

High altitude flights give you a considerably higher dose. Increasing the altitude by 40% doubles the hourly dose for passenger & crew.

# Annual Dose of Air Crew (1960-2005)

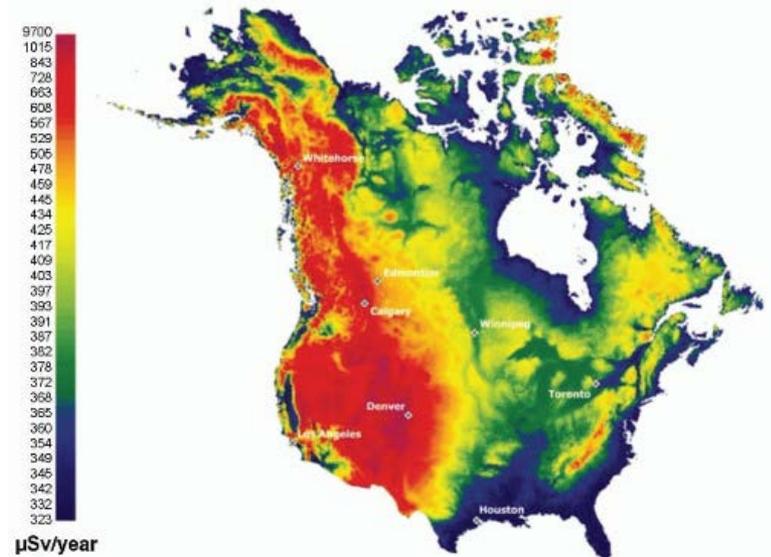

The average CR annual dose of air crew personnel is 1.5 mSv (150mRem), your annual dose CR in South Bend is: 0.3 Sv (30 mRem)  
 The mortality rate of air crews on cancer and other sicknesses is significantly lower in comparison of general population (same age group). No statistically significant increase in cancer rate has been observed.

# Cosmic Ray Intensity Distribution

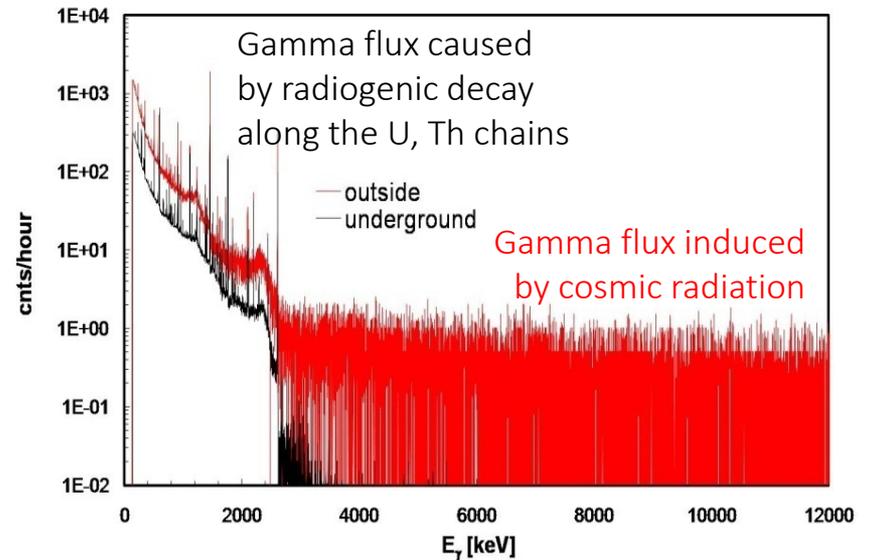

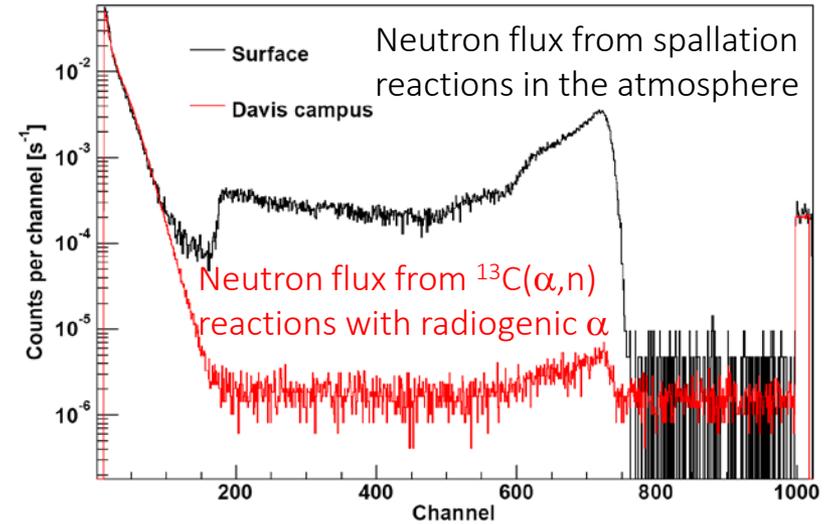

The annual outdoor effective dose ( $\mu\text{Sv}$ ) from cosmic radiation for Canada and the U.S.

— R.L. Grasty and J.R. LaMarre

The average annual cosmic ray dose is 0.4 mSv. Higher Dose is associated with altitude but also with the latitude of locations due to the funneling effects of the earth magnetic field.

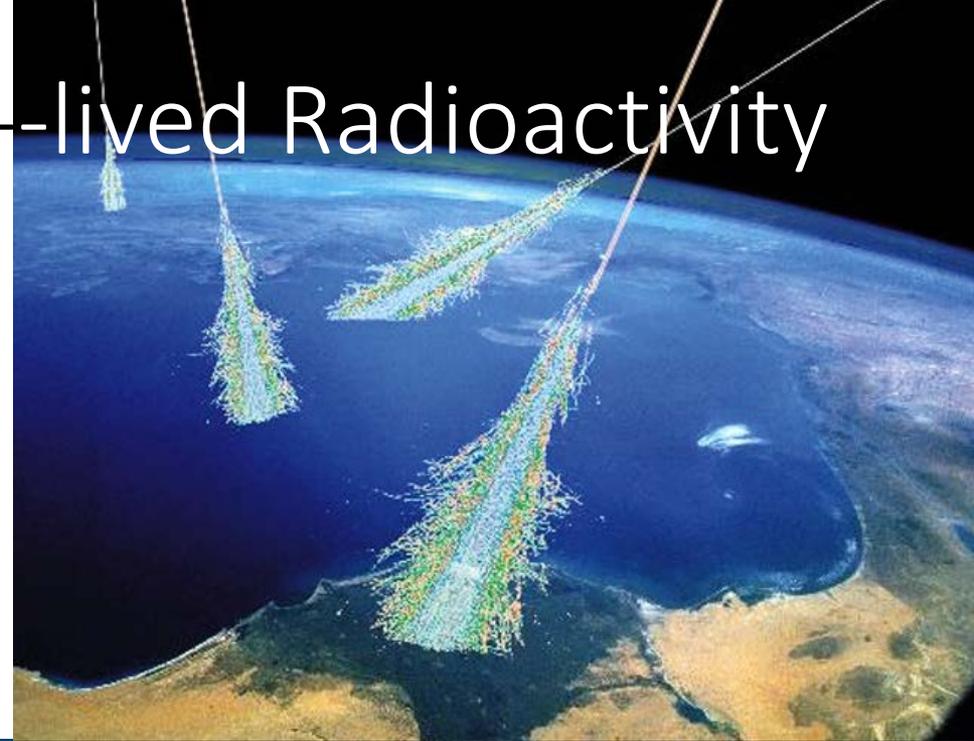

# Rock Shielding Underground

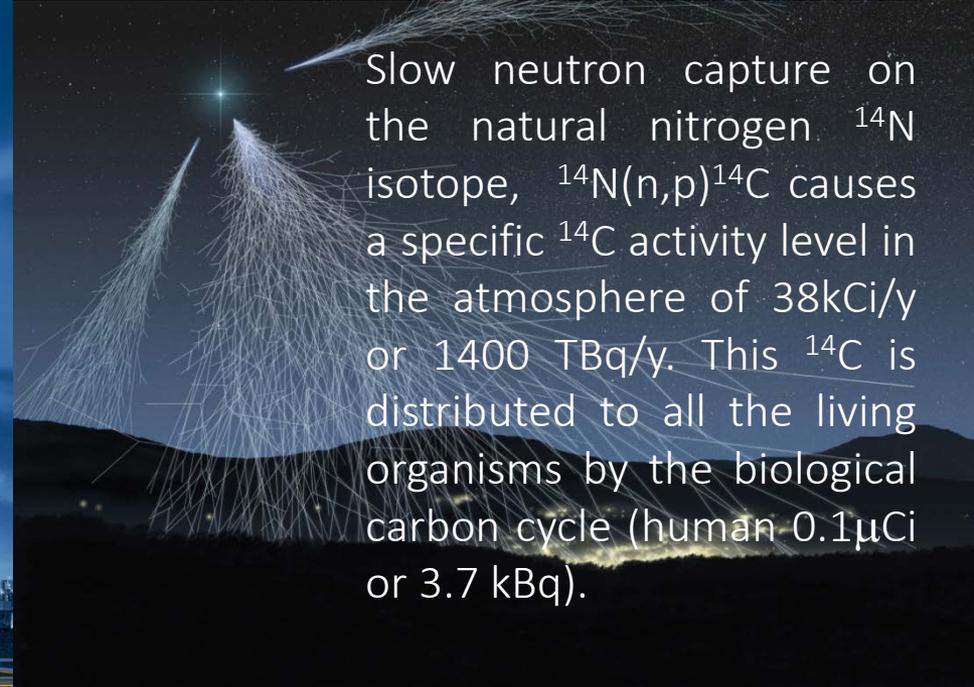

# Production of long-lived Radioactivity by Cosmic Rays

Primary radioactive products of cosmic ray spallation are  $^3\text{H}$  (tritium)  $T_{1/2}=12\text{y}$  and  $^{14}\text{C}$  ( $T_{1/2}=5730\text{y}$ ). Spallation occurs mainly on  $^{14}\text{N}$  and  $^{40}\text{Ar}$  isotopes in the atmosphere, the increase of radiogenic Ar caused an increase of cosmic rays induced radioactivity.

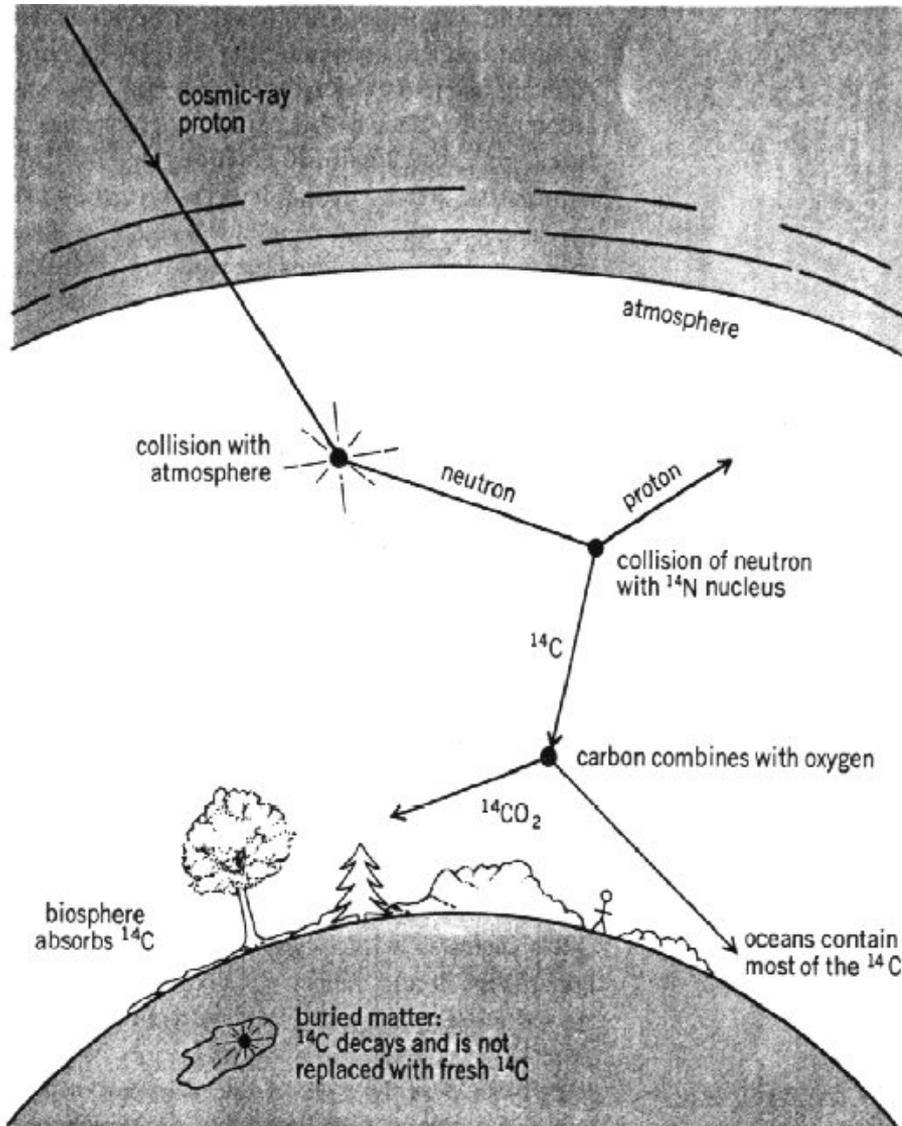

Tritium is produced by fast neutrons ( $>4\text{ MeV}$ ) e.g. by the  $^{14}\text{N}(n,t)^{12}\text{C}$  process (plus other reactions). It forms superheavy water HTO or  $\text{T}_2\text{O}$ . The global inventory prior to nuclear bomb tests was estimated to 26 MCi or  $9.6 \cdot 10^5\text{ TBq}$ .

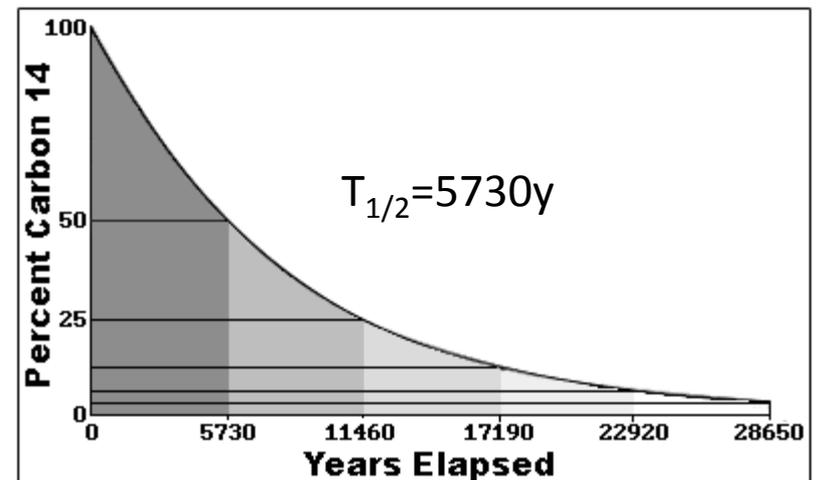

Slow neutron capture on the natural nitrogen  $^{14}\text{N}$  isotope,  $^{14}\text{N}(n,p)^{14}\text{C}$  causes a specific  $^{14}\text{C}$  activity level in the atmosphere of 38kCi/y or 1400 TBq/y. This  $^{14}\text{C}$  is distributed to all the living organisms by the biological carbon cycle (human  $0.1\mu\text{Ci}$  or 3.7 kBq).

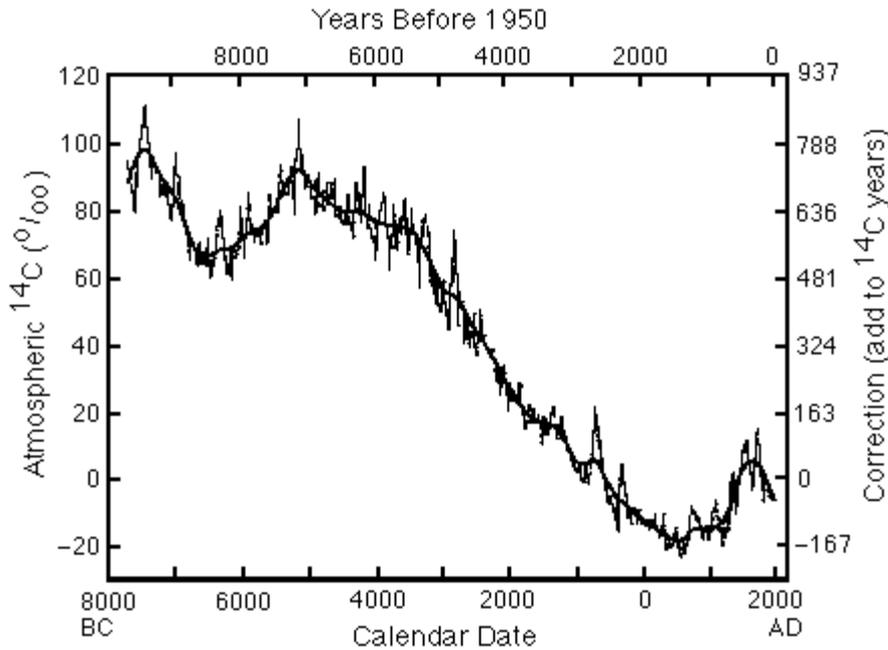

# $^{14}\text{C}$ Enrichment in Environment

$^{14}\text{C}$  is produced by the interaction of cosmic rays induced neutrons with  $^{14}\text{N}$  in the atmosphere through the  $^{14}\text{N}(n,p)^{14}\text{C}$  reaction. The  $^{14}\text{C}$  behaves chemically like regular carbon and is implemented in regular carbon cycle with an abundance that depends on the production rate. This depends on the cosmic ray flux, the abundance of  $^{14}\text{N}$  in the atmosphere and the reaction probability. The  $^{14}\text{C}$  decays but is continuously replenished by solar activity

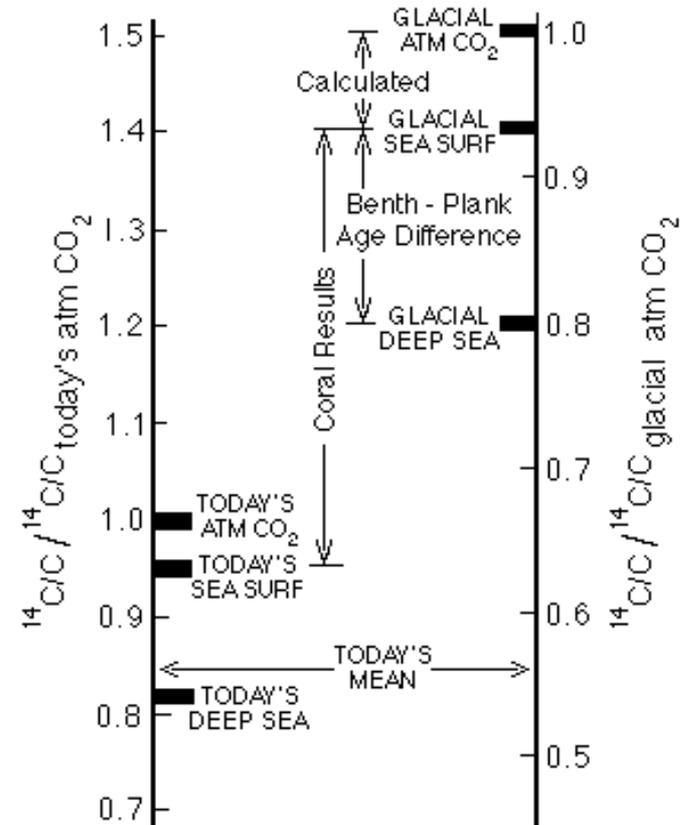

# $^{14}\text{C}/^{12}\text{C}$ Ratio in Atmosphere

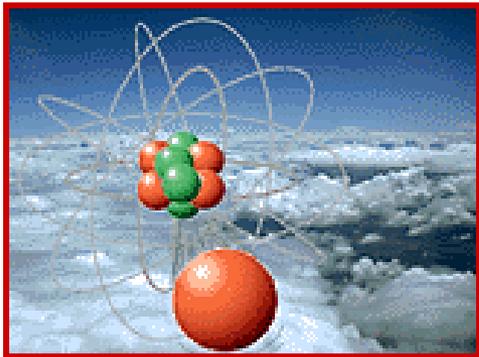

Based on ice-and tree-ring calibrations it was determined that  $^{14}\text{C}/^{12}\text{C}$  ratio is not constant with time, but shows long term fluctuations!

The fluctuation are due to solar distance and direction, variation in earth magnetic field, climatic conditions etc

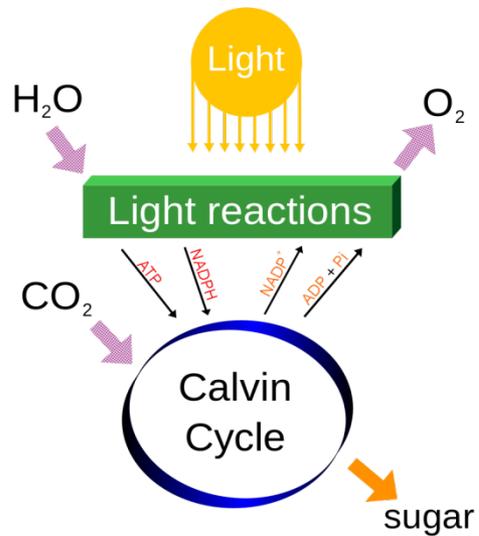

Average ratio:  $^{14}\text{C}/^{12}\text{C} = 1.3 \cdot 10^{-12}$

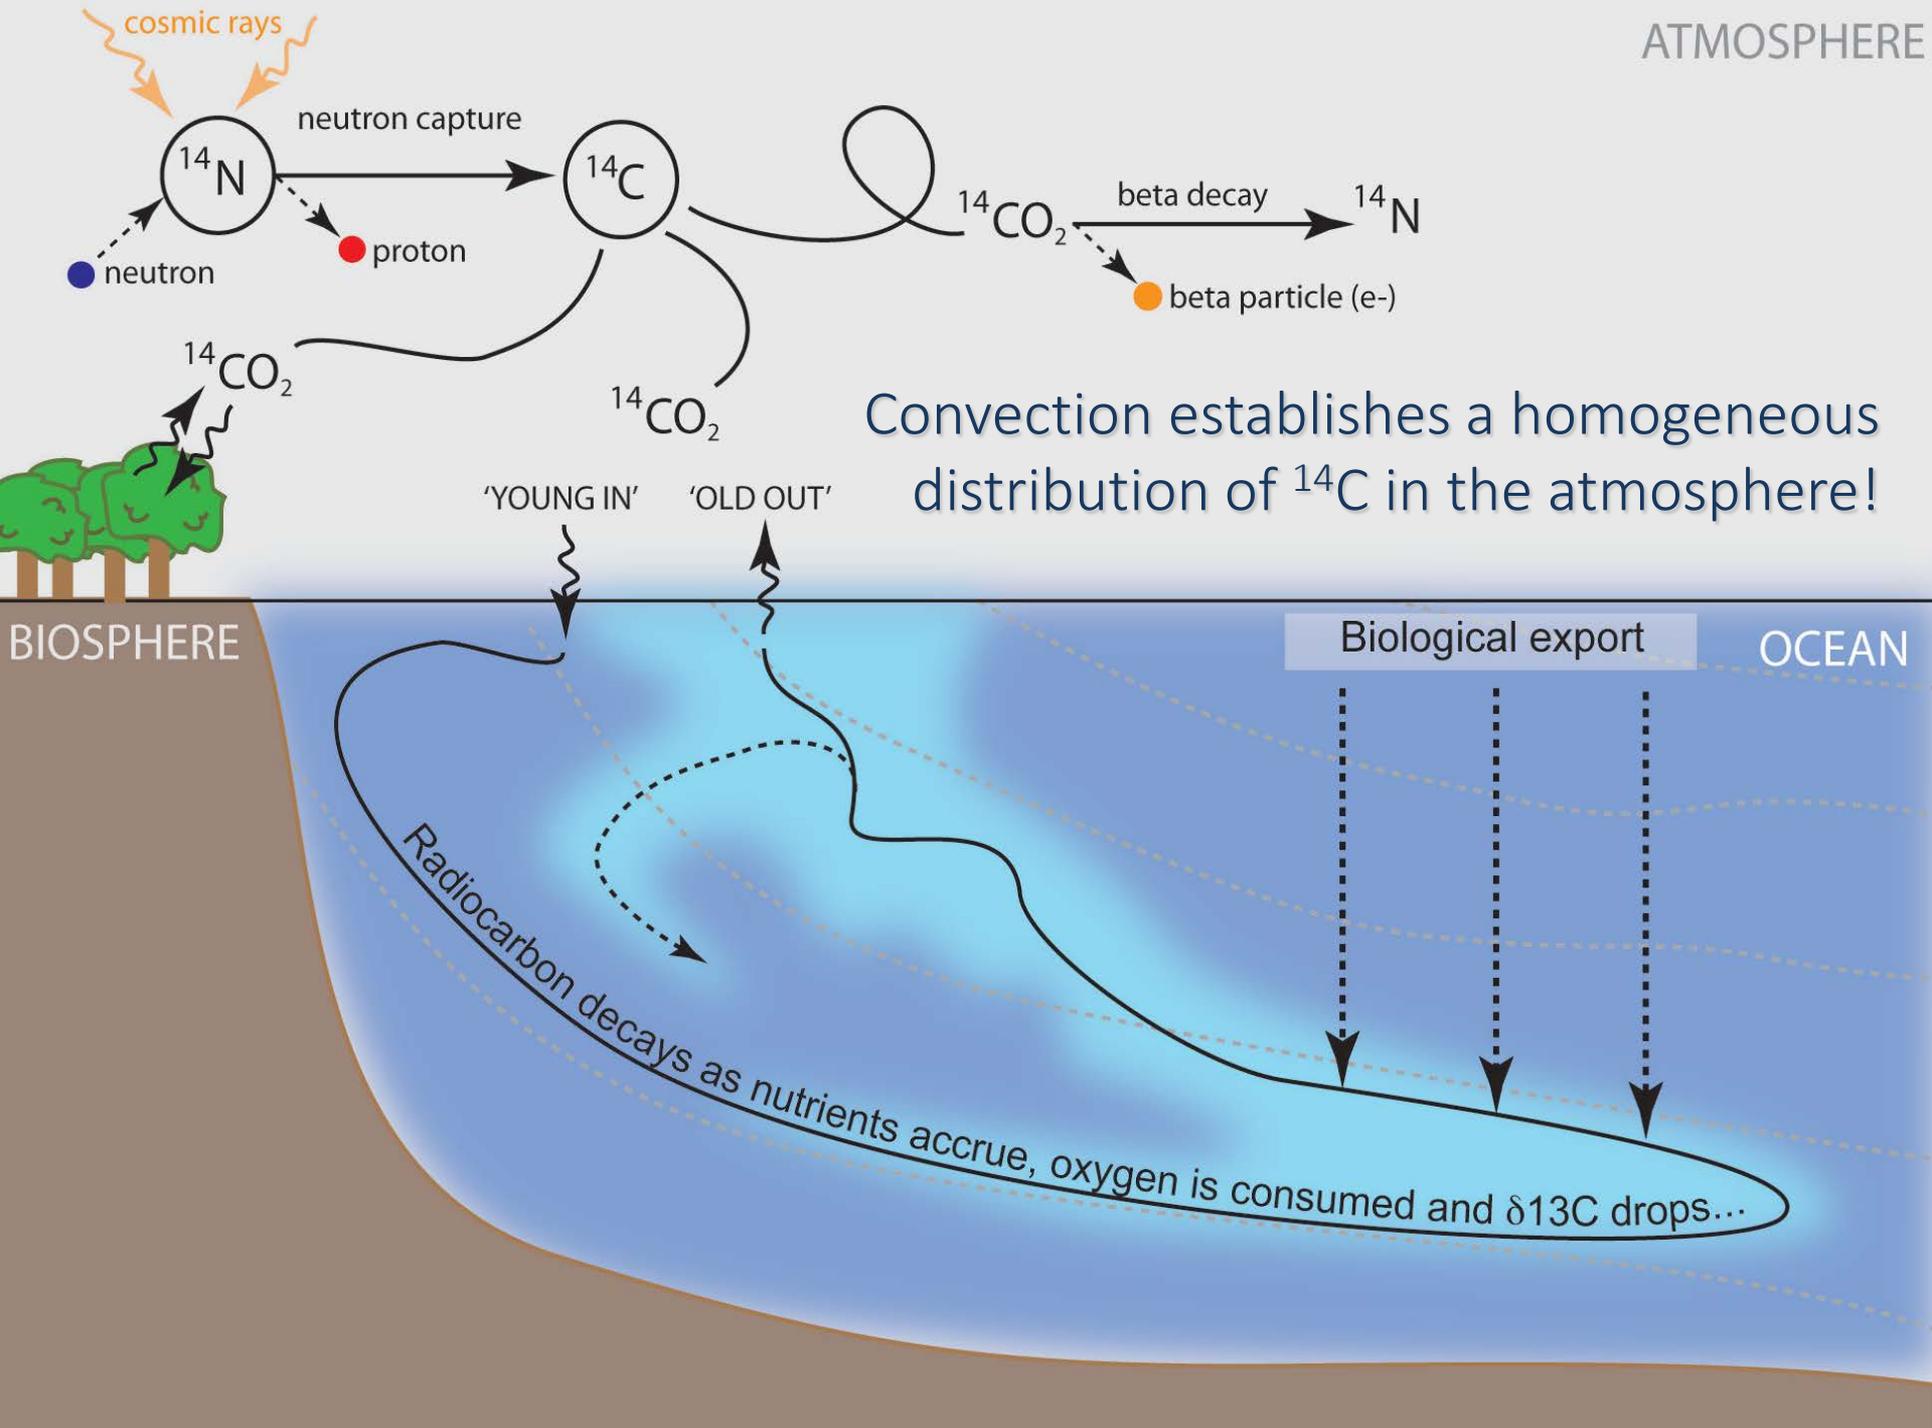

# $^{14}\text{C}$ Content in Atmosphere and Human

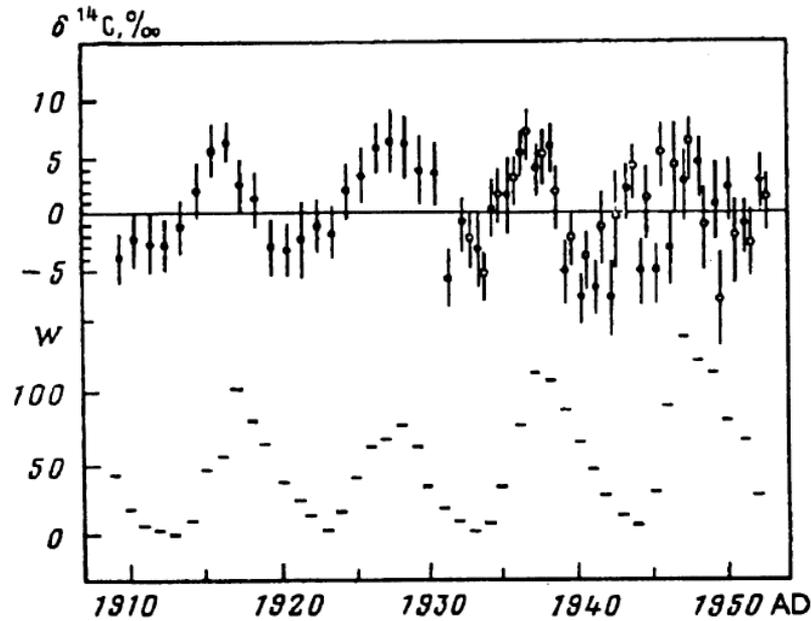

The production rate of  $^{14}\text{C}$  due to the  $^{14}\text{N}(n,p)^{14}\text{C}$  process is about 22000  $^{14}\text{C}$ -Isotopes per second and square meter. Taking the decay constant of  $\lambda = \ln 2/5730 \text{ y} = 1.21 \cdot 10^{-4} \text{ y}^{-1}$ , the production of  $^{14}\text{C}$ -radioactivity is approximately 2.66 Bq/y  $\text{m}^2$ . That translates into an annual production of 1.4 PBq, 1400 Trillion Becquerel in the earth atmosphere. This radioactivity becomes part of the biological carbon cycle.

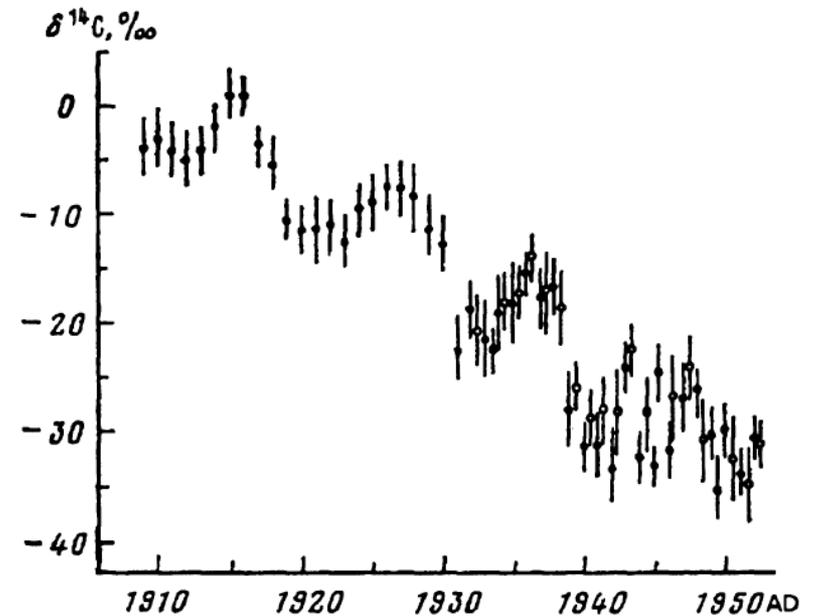

- It forms  $^{14}\text{CO}_2$  by chemical reaction with atmospheric oxygen
- It is absorbed by plants through photosynthesis with the  $^{14}\text{C}$  becoming part of the plant chemistry
- It is eaten by man or cow becoming part of the human body system

# Short-term fluctuations of the $^{14}\text{C}/^{12}\text{C}$ Ratio in Atmosphere

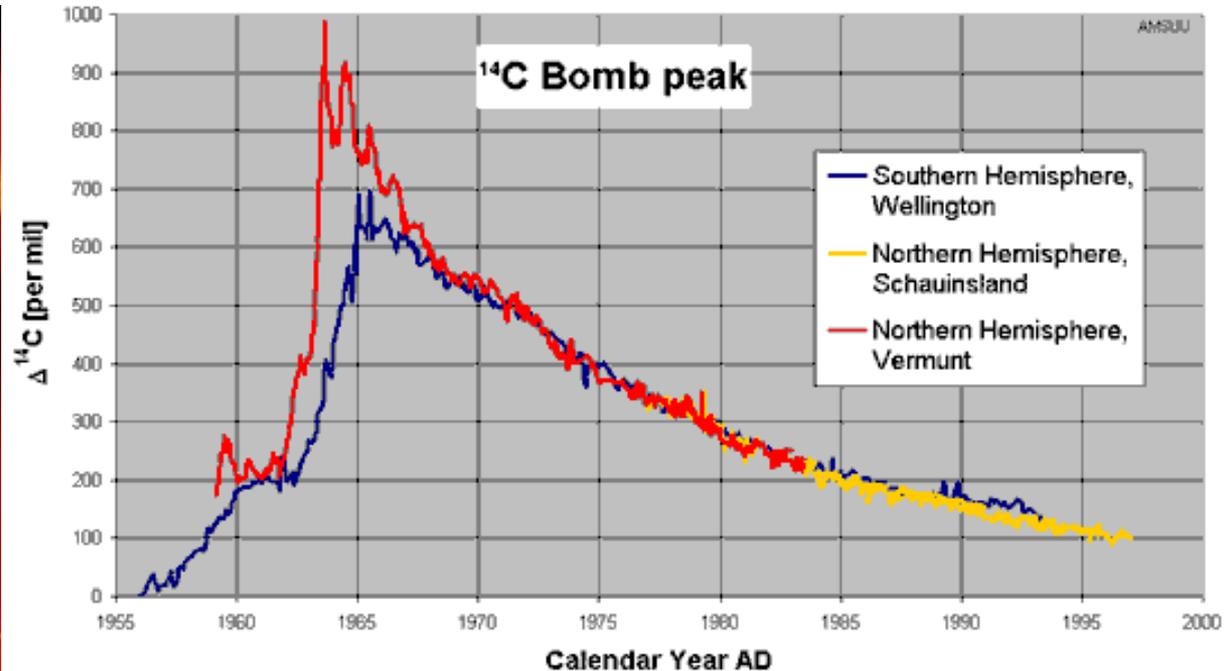

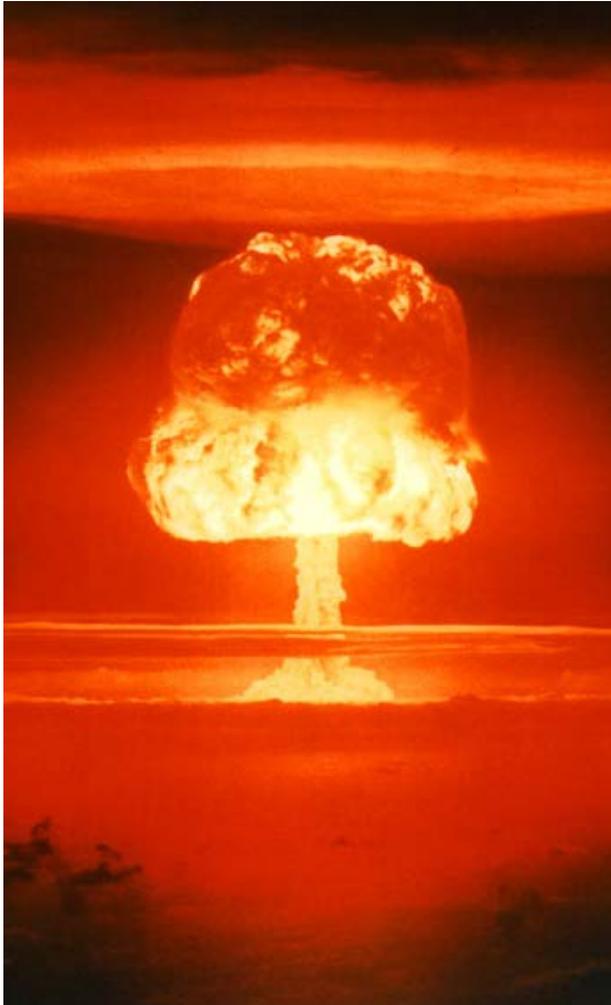

Fluctuation of  $^{14}\text{C}$  content in vintage wine (upper curve) due to the 11 year cycle of solar activity that provides the cosmic ray flux (lower curve) responsible for the  $^{14}\text{C}$  production. The  $^{14}\text{C}$  curve is normalized to a constant value for better comparison.

Un-normalized curve of  $^{14}\text{C}$  in vintage wine, the overall decline in  $^{14}\text{C}$  content reflects the increase of carbon emission from fossil (old) fuel burning deposited into the atmosphere and in due turn into the wine.

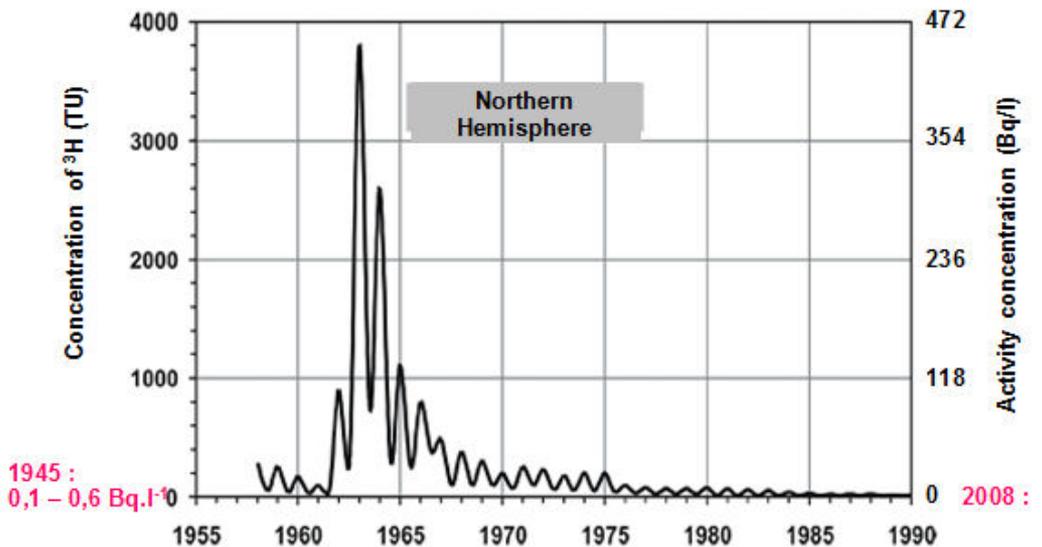

# Anthropogenic $^{14}\text{C}$ fluctuation

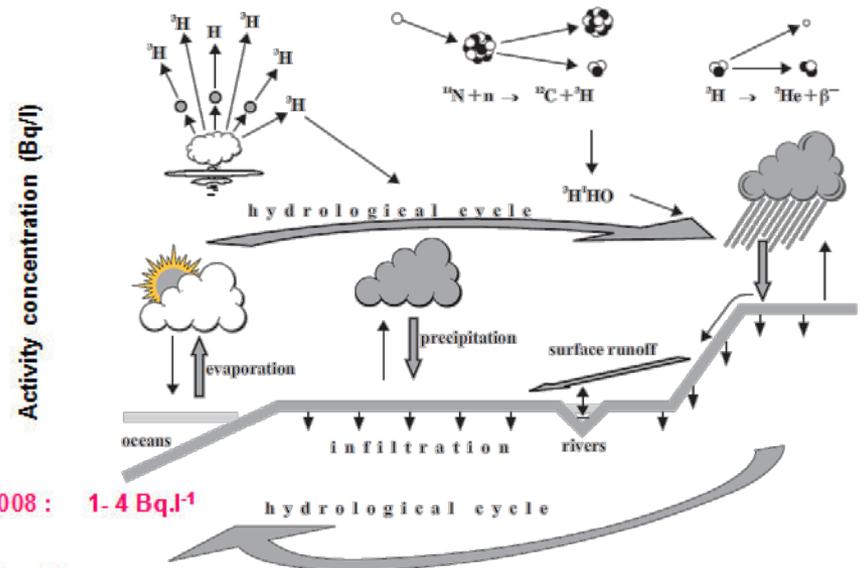

The physical half-life of  $^{14}\text{C}$  is 5730 years but the produced  $^{14}\text{C}$  activity is falling off much faster with an half life of about 10 years. This reflects the absorption capability of the earth environmental system, ocean, plants, animals.

# Tritium Production and the Tritium Peak

Pre-war cosmic ray bombarded generated natural tritium via the reaction  $^{14}\text{N}(n,t)^{12}\text{C}$  at a rate of 0.1-0.6Bq/l. In equilibrium between production and decay, the average annual production of tritium in the atmosphere is  $72 \cdot 10^{15}$  Bq or 72 PBq. The tritium isotope couples chemically with oxygen forming heavy radioactive water that participates at the water cycle in the hydrosphere. The average tritium activity in the atmosphere is 1 Exa-Becquerel or a quintillion ( $10^{18}$ ) Becquerel. 90% in water and 10% in water vapor or clouds. The ratio of tritium to hydrogen is defined in TU: 1 TU is the *ratio* of 1 tritium to  $10^{18}$  hydrogen atoms.

Smooth curve showing the average  $^3\text{H}$  concentrations in precipitation over the continental surface in the Northern hemisphere. *Source = IAEA Isotope hydrology, 2006*
